Abstract

The intracellular distribution of synthetic glycosphingolipids (GSLs) bearing a fluorophore can be monitored in living cells by fluorescence microscopy. We reported previously that variation in the length of the long-chain base and in the structure of the carbohydrate-containing polar head group of (2S,3R) (or β-erythro-)β-lactosylceramide (LacCer) did not alter the mechanism of endocytic uptake from the plasma membrane of various mammalian cell types [Singh, R.D., Puri, V., Valiyaveettil, J.T., Marks, D.L., Bittman, R.,Pagano, R.E., 2003. Selective caveolin-1-dependent endocytosis of glycosphingolipids. Mol. Biol. Cell 14, 3254–3265]. To extend our examination of the molecular features in LacCer that are responsible for its uptake by the caveolar-requiring endocytic pathway, we have synthesized the three unnatural stereoisomers [(2R,3R)-, (2S,3S)- and (2R,3S)-] of dipyrromethene difluoride (BODIPY™)-LacCer. These analogues will be used to probe the role of stereochemistry in the long-chain base of LacCer in the mechanism of endocytic uptake.

1. Introduction

A boron dipyrromethene difluoride (BODIPY™) (Johnson et al., 1991) fluorophore linked to the long-chain base of naturally occurring (2S,3R)-β-lactosylceramide (LacCer) via the α end of a N-pentanoyl moiety (compound a in Fig. 1) has been used to examine the intracellular trafficking of this and other glycosphingolipids (GSLs) in normal and disease cell types (Pagano et al., 2000). This GSL was localized in lysosomes of a diseased cell type, but was observed at the Golgi complex in normal fibroblasts (Chen et al., 1998). (2S,3R)-C5-BODIPY™-LacCer (which is available commercially) and a synthetic analogue bearing a maltosyl polar head group (2S,3R)-C5-BODIPY™-MalCer, utilized the same caveolar-dependent endocytic pathway for uptake from the plasma membrane of different cells (Singh et al., 2003; Bittman, 2004). In contrast, BODIPY™-sphingomyelin utilizes both a clathrin-dependent and a caveolar-dependent pathway in approximately equal extents for internalization (Puri et al., 2001). To examine the role of stereochemistry at C2 and C3 of the sphingosine chain of LacCer in determining the mechanism of endocytosis, we have prepared the following unnatural stereoisomeric analogues: (2R,3R)-, (2S,3S)-, and (2R,3S)-BODIPY™-LacCer (compounds b–d in Fig. 1).

Invitrogen/Molecular Probes (Eugene, OR); N-Boc-d-serine and diisobutylaluminum hydride (DIBAL-H, a 20 wt.% solution in toluene), Acros (Morris Plains, NJ); \(L\)-threo-sphingosine, Avanti Polar Lipids (Alabaster, AL); 1-pentadecyne, \(p\)-toluenesulfonic acid monohydrate (\(p\)-TsOH), and sodium bis(2-methoxyethoxy)aluminum hydride (Red-Al, a 70%, w/w solution in toluene), Alfa Aesar/Lancaster (Pelham, NH); \(L\)-threo-sphingosine, Avanti Polar Lipids (Alabaster, AL); 1-pentadecyne, \(p\)-toluenesulfonic acid monohydrate (\(p\)-TsOH), and sodium bis(2-methoxyethoxy)aluminum hydride (Red-Al, a 70%, w/w solution in toluene), Alfa Aesar/Lancaster (Pelham, NH); /H9252-d-lactosyl octaacetate, triphenylphosphine, trichloroacetonitrile, tert-butyldiphenylsilyl chloride (TBDPSCl), hydrazine acetate, benzoic anhydride, BF\(_3\)·OEt\(_2\), imidazole, 4-(dimethylamino)pyridine (DMAP), and \((n\)-Bu\(_4\))NF (TBAF), Sigma–Aldrich. Trifluoromethanesulfonyl azide (TfN\(_3\)) was prepared according to Vasella et al. (1991). Hepta-O-acetyllactosyl-1-trichloroacetimidate (compound 13) was synthesized from per-O-acetyllactose as described (Amvam-Zollo and Sinay, 1986).

Molecular sieves (300AW) were dried for 5 h at 150 °C and stored under vacuum over P\(_2\)O\(_5\).

2.1.2. General methods
Air- and moisture-sensitive reactions were carried out under nitrogen in flame-dried glassware. THF and toluene were distilled from sodium/benzophenone and calcium hydride prior to use. DMF was dried over calcium hydride. TLC was performed using aluminum-backed or glass-backed silica gel 60 F254 plates (0.25-mm thick), and the compounds were visualized by charring with 10% H\(_2\)SO\(_4\) in EtOH or by UV light. Column chromatography was carried out with silica gel 60 (230–400 mesh) using the elution solvents indicated in the text. Suspended silica gel was removed by filtration through an Osmonics Cameo filter (Fisher Scientific, Pittsburgh, PA). The \(^1\)H and \(^{13}\)C NMR spectra were recorded at 400 and 100 MHz, respectively, and were referenced to the residual CHCl\(_3\) at \(\delta 7.24\) (\(^1\)H) and the central line of CDCl\(_3\) at \(\delta 77.0\) ppm (\(^{13}\)C). Optical rotations were measured on a digital polarimeter at room temperature in the solvents stated.

4. Summary

The (2R,3R) (or o-3R, compound 20) sphingosines were synthesized as outlined in Schemes 2 and 5, respectively, by the reaction of (R)-Garner aldehyde (compound 4) (Garner et al., 1988; Garner and Park, 1987; Garner and Park, 1992) with lithium pentadecyne in the presence of zinc bromide in Et2O or HMPA in THF (Herold, 1988), respectively. (R)-Garner aldehyde was prepared (see Scheme 1) from N-Boc-d-serine (1), which was converted to its methyl ester and then treated with 2,2-dimethoxypropane in the presence of p-toluenesulfonic acid in benzene, followed by DIBAL-H reduction at −78 °C. The oxazolidine ring was opened with Amberlyst 15 resin, and Red-Al reduction (Van Overmeire et al., 1999) of the propargylic alcohol in Et2O afforded (2R,3R)- and (2R,3S)-N-Boc-sphingosines (compounds 7 and 19, respectively). The diazo transfer reaction afforded the stereoisomeric 2-azido sphingosine derivatives, compounds 9, 21, and 29. Silylation of the primary hydroxy group was carried out in the presence of 2 equivalents of imidazole; after benzoylation of the secondary hydroxy group, the desilylation reaction was performed at −23 °C (Mattjus et al., 2002), followed by rapid elution through a cold silica gel column, to minimize benzoyl migration, furnishing the three stereoisomers of 2-azido-3-benzoylsphingosines: compounds 12 (Scheme 3), 24 (Scheme 6), and 32 (Scheme 8). After BF3·OEt2-mediated lactosylation of the 2-azido-3-benzoylsphingosine stereoisomers with hepta-O-acetyllactosyl trichloroacetimidate in CH2Cl2 in the presence of molecular sieves, base-catalyzed deprotection afforded the β-lactosyl-2-azidosphingosines. Staudinger reduction of the azido group with triphenylphosphine in aqueous THF (Gololobov et al., 1981), followed by N-acylation with the N-hydroxysuccinimidy1 ester of BODIPY™-C5 and purification by column chromatography on silica gel (elution with CHCl3/MeOH 4:1, v/v), furnished the target unnatural BODIPY™-LacCer stereoisomers: compounds 16 (Scheme 4), 27 (Scheme 7), and 33 (Scheme 8). NMR spectroscopy and mass spectrometry confirmed the structures of these analogues.
